Chromogenic Listeria Differential Supplement

PRODUCT INFORMATION

N001-5g - Nalidixic Acid, Powder, 5g
N001-25g - Nalidixic Acid, Powder, 25g
N001-100g - Nalidixic Acid, Powder, 100g

P007-1MU - Polymyxin B Sulfate, Powder, 1MU
P007-10MU - Polymyxin B Sulfate, Powder, 10MU
P007-100MU - Polymyxin B Sulfate, Powder, 100MU

C059-1g - Ceftazidime Pentahydrate, Powder, 1g
C059-5g - Ceftazidime Pentahydrate, Powder, 5g

A007-100mg - Amphotericin B, Powder, 100mg
A007-250mg - Amphotericin B, Powder, 250mg
A007-1g - Amphotericin B, Powder, 1g
A007-5g - Amphotericin B, Powder, 5g

DESCRIPTION

Chromogenic Listeria Agar (ISO) is a medium for isolation, enumeration and presumptive identification of Listeria species and Listeria monocytogenes from food samples.

BACKGROUND

Nalidixic acid is the first of the synthetic quinolone antibiotics. Nalidixic acid is effective against both gram-positive and gram-negative bacteria. In lower concentrations, it acts in a bacteriostatic manner; that is, it inhibits growth and reproduction. In higher concentrations, it is bactericidal, meaning that it kills bacteria instead of merely inhibiting their growth.

Cycloheximide is an inhibitor of protein biosynthesis in eukaryotic organisms, produced by the bacterium Streptomyces griseus. Cycloheximide exerts its effect by interfering with the translocation step in protein synthesis (movement of two tRNA molecules and mRNA in relation to the ribosome) thus blocking translational elongation.

APPLICATION IN CHROMOGENIC LISTERIA AGAR (ISO)

Listeria monocytogenes is the most common pathogenic Listeria spp. and has been shown to be pathogenic to both man and animals. Some Listeria ivanovii strains also possess these enzymes and, although Listeria ivanovii are primarily pathogenic to animals, there are strains which have been shown to cause infection in humans. Studies have shown this medium to be superior to PALCAM medium for the isolation of Listeria monocytogenes.

Chromogenic Listeria Agar (ISO) uses the chromogen X-glucoside for presumptive identification of Listeria spp. This chromogen is cleaved by β-glucosidase, which is common to all Listeria species. Other organisms that possess this enzyme, such as enterococci, are inhibited by the selective agents within the medium: lithium chloride, polymyxin B and nalidixic acid, whilst amphotericin inhibits the growth of yeasts and moulds that may be present in the sample. Listeria monocytogenes and pathogenic Listeria ivanovii are then further differentiated by their ability to produce the phospholipase enzymes PIPLC and PCPLC which hydrolyse phosphatidylinositol or lethicin in the medium, producing an opaque white halo around the colony.

This medium is designed to identify Listeria spp. based on their utilisation of a chromogenic substrate. Chromogenic Listeria Agar (ISO), when used with Chromogenic Listeria Selective Supplement (ISO) and Chromogenic Listeria Differential Supplement (ISO) following the manufacturer's instructions, conform to the formulation described by Ottaviani and Agosti (ALOA) in ISO 11290-1:1997 (Incorporating Amendment No.1). This ALOA formulation incorporates phosphatidylinositol so that phosphatidylinositol phospholipase C (PIPLC), produced by Listeria monocytogenes, is detected. Alternatively, adding lecithin (Modified Chromogenic Listeria Differential Supplement) instead of phosphatidylinositol means that phosphatidylcholine phospholipase

Mechanism of action
C (PCPLC) activity can be detected. Both PIPLC and PCPLC are associated with the virulence of Listeria and, therefore, detection of either enzyme is a useful indicator of pathogenicity.

* Adjusted as required to meet performance standards
† Please use Chromogenic Listeria Differential Supplement (ISO) or Modified Chromogenic Listeria Differential Supplement in accordance with method being followed

**Method**

**Preparation**

**Modified ISO Formulation**

Suspend appreciate mount of Chromogenic Listeria Agar (ISO) in distilled water. Mix well and sterilise by autoclaving at 121°C for 15 minutes. Cool the medium to around 50 °C, and add Chromogenic Listeria Selective Supplement (ISO), re-suspended as directed, and Chromogenic Listeria Differential Supplement (ISO). Mix well and pour into sterile Petri dishes.

**Protocol**

Chromogenic Listeria Agar (ISO) can be used following a variety of enrichment procedures i.e. ISO, NMKL, FDA, AFNOR (UNI 03/04 - 04/054), etc.

The following method is a summary of ISO 11290-1:1997 (Incorporating Amendment No. 1):

1. Add 25 g of food sample to 225 ml of half fraser broth and stomach for a minimum of 30 seconds to mix the sample.

2. Incubate the broth without agitation at 30°C for 24 ± 3 hours.

3. Gently agitate the bag then, using a microbiological loop inoculate onto Chromogenic Listeria Agar (according to Ottaviani and Agosti) and a second selective medium (e.g. PALCAM Agar). Incubate at 37°C for 24h ± 3h, and if necessary for an additional 24h ± 3h (PALCAM Agar should be incubated under micro-aerobic conditions for best results).

4. Examine the PALCAM plate for black colonies and the chromogenic listeria agar plate for blue colonies with and without halos.

5. From the same incubated half fraser broth remove 0.1 ml and inoculate into 10 ml of Fraser broth. Incubate at 37°C for 48h ± 3h and then repeat Steps 3 & 4 followed by step 6.

6. Confirm presumptive colonies on the agar plates as Listeria monocytogenes or Listeria spp. by appropriate methods - refer to ISO 11290-1:1997 (Incorporating Amendment No.1)

**Quality control**

Positive control:

*Listeria monocytogenes* ATCC®7644: Good growth: blue/green plus halo

*Listeria innocua* ATCC®33090: Good growth: blue/green no halo

Negative control:

*Enterococcus faecalis* ATCC®29212: Inhibited
